CAPSTONE PROJECT REPORT

ON

SPATIO-TEMPORAL ANALYSIS OF NATIONAL POWER GENERATION

K. POOJITHA (1111-24-559-018)

Capstone Project Report submitted for the award of MSc Data Science II year

BY

OSMANIA UNIVERSITY, HYDERABAD-500007

Kasturba Gandhi Degree & PG College for Women

Accredited with A+ Grade by NAAC

Department of Statistics, Secunderabad-500026

DECLARATION

I hereby declare that I have successfully completed the project titled

Spatio-Temporal Analysis of National Power Generation

in Kasturba Gandhi Degree & PG College for Women.

Name	Class	Roll No	Signature
K. POOJITHA	II Year Sem-IV	1111-24-559-018	

This project has been done under the guidance of Ms. Ch. Vidhatri and supervision of Dr. A. Lalitha Devi, Head of the Department, Statistics, Kasturba Gandhi Degree & PG College for Women. This project was completed to my satisfaction and I have shown keen interest and dedication to the project. The project has been done from January 2026 to June 2026.

CERTIFICATE

This is to certify that K. POOJITHA (1111-24-559-018) pursuing her M.Sc. II Year Data Science, Kasturba Gandhi Degree & PG College for Women, Secunderabad have successfully completed her project on **"Spatio-Temporal Analysis of National Power Generation"** from our organization. This work is original and has been done with secondary data.

We wish her a successful and bright future.

H.O. D **PRINCIPAL**

INTERNAL EXAMINER **EXTERNAL EXAMINER**

ACKNOWLEDGEMENTS

At the outset, I thank the almighty for enabling me to carry out the research work successfully. I wish to thank the Management and the Principal Dr. R. Rajshree, Kasturba Gandhi Degree and PG College for Women, Secunderabad for their continuous support and encouragement to complete this work. My special thanks to Dr. A. Lalitha Devi, Head, Department of Statistics, Kasturba Gandhi Degree and PG College for Women for her timely help, guidance, and advice during our project.

My special thanks to Ms. Ch. Vidhatri, Assistant Professor, Department of Statistics, Kasturba Gandhi Degree and PG College for Women.

My heartful thanks are extended to my parents for their inspiration, moral support, and everlasting affection without which I would not have completed this project.

ABSTRACT

The Power Generation Patterns across India to uncover the core factors driving regional production efficiency and growth volatility. By analyzing a multi-variable longitudinal dataset, the study explores how different energy sources, seasonal changes, and administrative structures—such as individual States and Union Territories—shape national power sector dynamics. Through advanced statistical modeling and time-series techniques, the research maps production trends, measures infrastructure expansion, and evaluates the reliability of various energy categories within the grid. The findings reveal that administrative categorization and energy source selection heavily influence generation consistency and sectoral growth. The study successfully identifies high-performing regional clusters and calculates annual growth trajectories to support long-term energy planning. By bridging the gap between raw data and practical intelligence, this evidence-based approach provides policymakers with a robust framework to optimize resource allocation, enhance grid resilience, and build a more stable, sustainable power infrastructure across all regions.

Keywords: Electricity Generation, Production Efficiency, Statistical Modeling, Renewable Energy Transition, Panel Vector Autoregression (Panel VAR) , Time-Series Forecasting.

CHAPTER-1

INTRODUCTION

1.1 INTRODUCTION

Electricity generation is the backbone of modern infrastructure, playing a fundamental role in the economic and social development of a nation. It powers the movement of industries, supports the delivery of essential services, and is a primary driver of overall national growth. In India, rapid industrialization, urbanization, and a growing population have led to a continuous surge in energy demand, necessitating a highly reliable and efficient electricity supply. However, this growth also brings significant challenges, particularly in managing the transition toward cleaner energy sources while ensuring grid stability and regional equity in power distribution. Electricity production is vital for the standard of living, and its stable supply directly impacts healthcare, education, trade, and the national economy. Consequently, optimizing generation efficiency and ensuring a balanced energy mix have become top priorities for energy authorities and policymakers.

The performance and efficiency of electricity generation are influenced by a multitude of variables. Temporal factors such as seasonality and annual consumption cycles significantly impact production levels, while categorical differences in energy sources—ranging from traditional thermal power to emerging renewable technologies—determine the sustainability and reliability of the grid. Similarly, regional characteristics, administrative structures (such as the distinction between States and Union Territories), and localized infrastructure play a critical role in determining output capacity and growth volatility. Understanding the complex interplay between these factors is essential for developing effective energy strategies and ensuring long-term energy security.

Traditionally, energy studies have focused on analyzing historical production records to assess basic trends and growth rates. While these studies provide foundational knowledge, they often struggle to identify the nuanced relationships among regional dynamics, temporal variations, and the shifting composition of the energy mix. With the increasing availability of granular energy data, there is a growing necessity to adopt advanced analytical techniques that can provide deeper, data-driven insights.

By applying robust statistical techniques and analytical modeling, it is possible to uncover hidden production patterns, classify regional efficiency, and evaluate the stability of various energy

sources. These insights can assist energy authorities in identifying high-performing regions, optimizing the energy portfolio, and implementing targeted infrastructure strategies based on empirical evidence. The present study focuses on the comprehensive analysis of electricity generation performance using data science and statistical modeling techniques. A detailed dataset containing geographic identifiers, temporal records, production values, and year-over-year growth metrics was analyzed to examine generation patterns and identify the factors influencing regional production efficiency. The study employs descriptive statistics, compositional analysis, time-series testing, and rigorous statistical modeling to generate meaningful insights that support evidence-based decision-making and contribute to the sustainable development of India's energy sector.

1.2 MOTIVATION OF THE TOPIC

The increasing demand for efficient energy management and the need to understand electricity usage patterns in a rapidly developing country. India's growing population, industrial expansion, and increasing dependence on electricity make it important to analyze consumption trends and identify factors influencing energy demand. Analyzing this dataset allows for the identification of regional consumption trends and peak demand cycles, directly supporting efficient resource allocation and grid load balancing. This project provides a practical framework to apply data science techniques toward minimizing power waste, streamlining utility operations, and advancing sustainable energy management across India.

1.3 SIGNIFICANCE

Reliable electricity generation is the cornerstone of economic stability and national progress. As nations worldwide undergo massive energy transitions, understanding the dynamics of power production has become a critical international priority. The significance of this study lies in its ability to transform raw, high-dimensional energy data into actionable intelligence, bridging the gap between historical production records and future energy planning across both domestic and global markets. By identifying regional efficiency clusters, cross-border comparative trends, and quantifying growth volatility, this research provides essential insights for energy authorities, international policymakers, and infrastructure planners to optimize national and global energy mixes, enhance supply chain resilience, and ensure long-term grid stability on a global scale.

NEED OF THE STUDY

Rapidly rising power demand, frequent supply fluctuations, and the complexity of modern grid networks necessitate a shift away from traditional, reactive energy management toward predictive, intelligence-driven solutions. Without advanced analytical models, utilities struggle to anticipate peak consumption loads, minimize distribution losses, and efficiently allocate resources across diverse geographic regions. This project addresses these critical operational vulnerabilities by establishing a data-driven foundation to forecast energy behavior, bridge infrastructure gaps, and streamline power distribution. Ultimately, implementing these techniques is essential for modernizing energy frameworks, preventing regional power deficits, and ensuring a stable, resilient power supply for future industrial and domestic needs.

1.4 PROBLEM STATEMENT

Analyzing India's power sector reveals a core challenge: understanding how long-term production trends and legacy fossil-fuel variables drive emissions, while identifying sudden structural breaks and distinct state-level transition typologies that standard aggregations obscure. Furthermore, bridging historical performance with reliable short-term forecasting is essential for anticipating future generation trajectories and supporting evidence-based grid planning.

1.5 OBJECTIVES OF THE STUDY

The objectives of the present study are:

- To analyze long-term trends and identify key variables driving electricity production and emissions.
- To detect sudden structural shifts, change points, and regional classification typologies.
- To deploy time-series predictive modeling to forecast future electricity generation trends.

1.6 HYPOTHESIS

Null Hypothesis (H_0):

Long-term electricity generation trends show no significant directional growth, and key generation variables (such as legacy fossil fuels) do not exert a dominant influence on regional carbon performance.

Alternative Hypothesis (H_1):

Electricity generation exhibits a statistically significant long-term trajectory, and specific generation variables (such as coal dominance) act as primary structural drivers of regional emissions.

Null Hypothesis (H_0):

Regional power generation time-series contain no statistically significant structural change points, and Indian states exhibit uniform transition behavior without distinct multi-year clustering typologies.

Alternative Hypothesis (H_1):

Regional power sectors experience macro-level regime shifts with statistically significant inflection points, and Indian states can be reliably classified into distinct, multi-year clean energy transition typologies.

Null Hypothesis (H_0):

Historical monthly electricity generation time-series data contains a unit root (is non-stationary and exhibits no consistent deterministic trend or stable seasonal patterns), preventing reliable out-of-sample parametric forecasting.

Alternative Hypothesis (H_1):

Historical monthly electricity generation time-series data is stationary or difference-stationary with stable seasonal and temporal structures, enabling SARIMAX models to reliably capture these patterns and accurately forecast future out-of-sample generation trajectories.

CHAPTER-2

REVIEW OF LITERATURE

2.1 REVIEW OF LITERATURE

- Ghosh, Sajal (2009), "Electricity supply, employment and real GDP in India: evidence from cointegration and Granger-causality tests," Methods: Autoregressive distributed lag (ARDL) bounds testing and Granger-causality, Variables: Electricity supply, real GDP, and employment, Conclusion: Long-run equilibrium exists between electricity supply, GDP, and employment, with unidirectional causality from GDP and electricity supply to employment, Outcome: Established the electricity-growth nexus and demonstrated that supply-side measures can reduce energy wastage without hindering economic growth.

- Ahmad, S., & Wu, J. (2022), "Energy Demand Forecasting Using Fused Machine Learning Approaches," Methods: Support Vector Machine (SVM) and Deep Extreme Learning Machine (DELM), Variables: Power consumption, smart meter data, and feature-fused datasets, Conclusion: Decision-based fusion of machine learning models provides superior forecasting accuracy compared to individual models, Outcome: Achieved 90.7% accuracy in predicting energy consumption, providing a framework for intelligent energy management.

- Bhattacharyya, S. C. (2011), "Energy Access Programmes and Sustainable Development: A critical review," Methods: Multi-dimensional sustainability analysis and correlation mapping, Variables: Energy access, HDI, GNI per capita, and electrification rates, Conclusion: Electrification alone does not resolve energy access or sustainability issues; a rebalancing of approaches is required, Outcome: Highlighted the correlation between HDI and energy access, emphasizing that development must be socially and environmentally balanced.

- Mathur, A., et al. (2009), "Carbon emissions reduction strategies and poverty alleviation in India," Methods: Computable General Equilibrium (CGE) model, Variables: Carbon tax, economic growth, poverty, and emission permits, Conclusion: Domestic carbon taxes may increase poverty, whereas international tradable emission permits are more economically efficient, Outcome: Demonstrated that emissions reduction targets can be met without compromising poverty alleviation goals if revenue is transferred to the poor.

- Mishra, V., et al. (2009), "The relationship between economic growth and carbon emissions in India," Methods: Granger causality and ARDL model, Variables: GDP, CO2 emissions, oil consumption, and urbanization, Conclusion: Unidirectional causality exists from energy consumption and GDP to carbon emissions, Outcome: Proved that efforts to reduce carbon emissions without energy efficiency improvements would adversely affect India's economic.

- Jain, M., et al. (2019), "RE Integration in India: Flexibility Solutions," Methods: Comparative system analysis and grid connectivity modeling, Variables: Installed renewable capacity, tradable capacity (REC), and grid synchronization, Conclusion: A significant gap exists between installed renewable capacity and actual grid-integrated tradable power, Outcome: Advocated for continuous, accurate forecasting and prioritized investment in grid flexibility solutions to enhance reliability.

- International Energy Agency (2021), "Renewables Integration in India 2021," Methods: System-level modeling and state-wise comparative analysis, Variables: Solar/wind penetration, demand-side flexibility, and grid storage, Conclusion: Challenges and priorities for renewable integration differ significantly across states, requiring tailored regulatory and market solutions, Outcome: Provided an international framework for maximizing the value of renewables in India's electricity system.

- Bose, S. (2019), "Machine learning algorithms in forecasting of photovoltaic power generation," Methods: Comparative assessment of neural networks and hybrid prediction strategies, Variables: PV power generation, meteorological data, and seasonal variations, Conclusion: Seasonal variations significantly affect the accuracy of all machine learning models, but hybrid strategies perform best, Outcome: Developed a comparative benchmark for PV forecasting methods in power systems.

- ResearchGate (2024), "Analysis of control and computational strategies for green energy integration," Methods: Computational optimization and state-of-the-art control mechanisms, Variables: Hybrid power networks, frequency regulation, and load demand, Conclusion: Grid

stability in hybrid networks requires advanced control strategies to manage the unpredictability of renewable sources, Outcome: Identified effective mechanisms for minimizing power imbalances in sociotechnical infrastructures.

- Naudé, W. (2011), "Climate Change and Industrial Policy," Methods: Policy analysis and literature review, Variables: Climate change, industrial policy, and economic growth, Conclusion: Climate change mitigation requires a strategic industrial policy that considers the trade-offs between emission reductions and industrial competitiveness, Outcome: Informed the development of inclusive green growth frameworks.

- Weitzel, M., et al. (2013), "Effects of international climate policy for India," Methods: National and global Computable General Equilibrium (CGE) models, Variables: Emission permits, economic growth, and global carbon policy, Conclusion: Global climate policy frameworks have distinct impacts on India's economic trajectory depending on the allocation of emission permits, Outcome: Provided insights into the impact of international trade on India's environmental sustainability.

- Ojha, V. P., et al. (2020), "Recycling carbon tax for inclusive green growth: A CGE analysis of India," Methods: CGE analysis, Variables: Carbon tax revenue, inclusive growth, and green energy investments, Conclusion: Recycling carbon tax revenue for the benefit of low-income households supports inclusive green growth, Outcome: Validated a policy pathway for reconciling environmental goals with social welfare.

- Stevens, P., & Dietsche, E. (2008), "Resource curse: an updated review," Methods: Literature review and empirical assessment, Variables: Resource abundance, economic development, and governance, Conclusion: Resource-rich economies often face governance challenges that impede sustainable development, Outcome: Highlighted the necessity of institutional quality in managing energy resources.

- Shahbaz, M., & Feridun, M. (2012), "Electricity consumption and economic growth empirical evidence from Pakistan," Methods: Cointegration and causality approaches, Variables: Electricity consumption and GDP, Conclusion: Electricity consumption is a vital driver of economic growth in emerging economies, Outcome: Provided a regional comparative perspective on energy-growth causalities.

- Lean, H. H., & Smyth, R. (2010), "Multivariate Granger causality between electricity generation, exports, prices and GDP in Malaysia," Methods: Multivariate Granger causality,Variables: Electricity generation, exports, prices, and GDP, Conclusion: The relationship between energy and economic variables is complex and multi-faceted, Outcome: Established a methodology for assessing causality in multivariate energy systems.

- Bhattacharya and Saxena (2015) investigated the regional inequalities in energy access across North India, highlighting how geographic and socio-economic factors contribute to disparities in the distribution of electricity. Their study emphasizes that regional energy poverty is not merely a consequence of supply shortages but is deeply influenced by localized administrative and demographic structures, providing a framework for understanding why different regions experience varying levels of energy reliability.

- Pargal and Banerjee (2014), in their comprehensive analysis of India's electricity distribution, evaluated the operational and financial performance of state utilities. Their work serves as a critical benchmark for identifying the "drivers of losses" in the power sector. By analyzing the structural differences between state-run utilities, they illustrated how administrative management directly affects generation efficiency and regional energy availability, supporting the need for state-specific performance indexing.

- The U.S. Energy Information Administration (EIA, 2020) examined the complexities of interregional electricity trade in India. Their study highlighted how grid regions differ significantly in their climatic conditions and consumption compositions (industrial vs. agricultural loads), leading to distinct seasonal and daily load shapes. The report emphasizes that transmission limitations often force regions to rely on local fossil-fuel-based generation,

creating a clear link between regional geography and production volatility.

- Azadeh and Ghaderi (2008) explored advanced analytical techniques for forecasting energy consumption in developing economies like India. By comparing conventional regression models with Artificial Neural Networks (ANNs), they demonstrated that high-dimensional data—which includes industrial output, population, and GDP—requires non-linear modeling to accurately capture production patterns. This study reinforces the shift toward using data science and machine learning to address the volatility inherent in electricity demand and supply.

- Ember (2026) provided a recent data-driven analysis of electricity transition performance across 21 Indian states. Their findings track the rapid deployment of renewable energy and identify specific "bottlenecks" in transmission and grid flexibility. By focusing on fiscal-year trends, their research highlights how individual states are capturing incremental demand through clean sources, offering a contemporary perspective on how regional production efficiency is evolving in the face of national decarbonization targets.

- Priyadarshini, S., & Kumar, R. (2024) explored the relationship between regional infrastructural investment and electricity production output in developing economies. By utilizing regression modeling, their research highlights those states with higher initial investments in smart grid technology exhibit significantly lower production volatility than those relying solely on legacy systems. Their findings provide a strong quantitative basis for arguing that regional administrative focus on grid modernization is the primary driver of consistent national energy performance.

2.2 COMPARISION STUDY

Ghosh (2009), Shahbaz and Feridun (2012), and Lean and Smyth (2010) primarily focused on analyzing macroeconomic interactions using cointegration frameworks, ARDL bounds testing, and multivariate Granger-causality models. These foundational studies established the critical "energy-growth nexus," proving that electricity supply and consumption act as vital drivers of real GDP and employment in emerging economies. The present study builds upon these methodologies by translating multi-variable longitudinal tracking into the context of state-level electricity generation, utilizing a robust dataset to investigate production efficiency and growth volatility across India.

Unlike many earlier studies that concentrated primarily on national macroeconomic aggregates, the present study extends the analytical scope by integrating advanced time-series econometrics, machine learning attribution, and unsupervised spatial clustering. While the reviewed literature heavily emphasizes standard cointegration, regression models, and macroeconomic CGE frameworks—such as those by Mathur et al. (2009), Weitzel et al. (2013), and Ojha et al. (2020) focusing on carbon taxes and green growth—this research deploys a specialized multi-tiered pipeline. This includes the Mann-Kendall Trend Test, Random Forest Feature Importance, Panel Vector Autoregression (Panel VAR), Hierarchical Agglomerative Clustering, and SARIMAX forecasting. This combination uncovers hidden temporal shifts, cross-state feedback loops, and structural transition typologies that go far beyond standard macroeconomic reporting.

The existing literature consistently highlights the operational and regional complexities of grid management. Bhattacharyya (2011), International Energy Agency (2021), Bhattacharya and Saxena (2015), and Pargal and Banerjee (2014) emphasized that regional energy access, utility performance, and decarbonization challenges vary drastically across states, heavily influenced by localized administrative structures and geographic distribution constraints. The current study aligns directly with these principles by evaluating variables such as coal, gas, and renewable generation outputs alongside state-level production volatility. Through non-parametric testing, econometric panel modeling, and clustering, the study provides concrete empirical evidence on how administrative choices drive infrastructure scale versus production volatility.

Previous research generally evaluated energy forecasting and stability from single-model machine learning or high-level international perspectives. For instance, Ahmad and Wu (2022) and Bose (2019) demonstrated the utility of support vector machines and neural networks for power forecasting, while Jain et al. (2019), EIA (2020), and Ember (2026) tracked the gaps in renewable integration, transmission bottlenecks, and state-wise clean energy transitions. Although these studies provide vital technological and regional foundations, they often lack a unified framework combining longitudinal structural shift detection, multi-variable shock propagation (Panel VAR), and localized typology clustering. The present study addresses this gap by combining the Mann-Kendall Trend Test, Random Forest attribution, Panel VAR, Hierarchical Agglomerative Clustering, and SARIMAX modeling to systematically evaluate and predict complex energy generation trajectories across Indian states and Union Territories.

Another essential distinction between prior literature and the present research lies in the operational synthesis of modern data science and econometric methodologies. Most foundational studies, including Azadeh and Ghaderi (2008) and ResearchGate (2024), highlighted the necessity of non-linear modeling and advanced control strategies for handling hybrid energy networks. In contrast, the present research integrates rigorous non-parametric trend verification, dynamic panel estimations, and seasonal forecasting into a single operational pipeline to support actionable, evidence-based decision-making.

Overall, the present study complements and extends the findings reported in the review of literature by bridging established macro-energy concepts with modern, high-performance analytical techniques. While previous studies confirmed that energy source choices, regional disparities, and technological factors heavily influence grid performance, the current research further quantifies these interactions and evaluates multi-step predictive trajectories using a robust longitudinal framework. By integrating exploratory data analysis, advanced statistical testing, and comparative machine learning modeling, the study delivers a comprehensive framework for understanding the core drivers shaping India's ongoing clean energy transition. Consequently, the research contributes not only to the existing body of literature on energy systems but also demonstrates the effectiveness of data science methodologies in guiding resilient, regionally targeted infrastructure strategies.

CHAPTER-3

DATA DOMAIN

3.1 DATA SOURCE

The dataset used in this study was obtained from the Kaggle platform and it is a Secondary data. The selected dataset, "Indian Electricity Consumption" contains 223,105 records and 13 variables.

VARIABLE DESCRIPTION

Variable Name	Description
Country	The name of the country where the data is recorded
Country Code	The standardized code representing the country
State	Name of the state or region where production occurred
State Code	The standardized code for the specific state
State Type	Administrative classification (e.g., State, Union Territory)
Date	The specific calendar date of the recorded observation
Category	High-level grouping of energy sources
Subcategory	Specific classification within the main category
Variable	The specific energy indicator being measured
Unit	The unit of measurement for the recorded value
Value	The numerical amount or level of the specified variable
YoY Absolute	Absolute difference in value compared to the previous year
YoY % Change	Percentage growth or decline relative to the previous year

CLASSIFICATION OF VARIABLES AND MEASUREMENT SCALES

Variable Name	Variable Type	Measurement Scale
Country	Categorical	Nominal
Country Code	Categorical	Nominal
State	Categorical	Nominal

Subcategory	Categorical	Nominal
Variable	Categorical	Nominal
Unit	Categorical	Nominal
Value	Numerical	Ratio
YoY Absolute	Numerical	Interval
YoY % Change	Numerical	Ratio

3.2 DATA DOMAIN

The data domain of this dataset falls under Energy Informatics and Macroeconomic Statistics, providing a structured, longitudinal framework for evaluating the performance and composition of India's power sector. By integrating geographic identifiers, detailed temporal records, and multi-dimensional production metrics—including absolute values and year-over-year growth rates—the dataset captures the complex interplay between national energy policy, regional production capacity, and the transition toward diverse energy sources. This domain is essential for multi-scalar analysis, enabling researchers to identify shifts in energy generation efficiency, assess the reliability of different power technologies across administrative jurisdictions, and quantify the volatility inherent in meeting a nation's growing energy demand over time.

CHAPTER-4

STATISTICAL TOOLS AND SOFTWARES USED

4.1 STATISTICAL TOOLS USED

- **Descriptive Statistics**

The descriptive statistics framework establishes the foundational integrity of the analysis through four core metrics. The Data Structure serves as the initial architectural assessment, defining the dimensions and variables available to ensure the study's scope is comprehensive. This is supported by an evaluation of Numerical Trends, which utilizes the mean, standard deviation, and range to quantify the scale of electricity generation and detect potential outliers that could skew the analysis. Furthermore, the Categorical Composition provides a systematic breakdown of the energy mix and regional distribution, allowing for the segmentation of data into logical groups for comparative study. Finally, the Overall Reliability metric calculates the percentage of data completeness, which acts as a vital quality control measure to confirm that the dataset is sufficiently robust for rigorous scientific inquiry and visualization.

- **Mann – Kendall Trend Test**

The Mann-Kendall Trend Test is a non-parametric statistical procedure used to detect monotonic trends in time-series data. It evaluates whether a variable consistently increases or decreases over time without making any assumptions about the underlying distribution, such as normality, making it particularly useful for environmental, meteorological, and climate-related datasets where data is frequently skewed or non-normally distributed.

- **Random Forest Feature Importance Attribution**

Random Forest Feature Importance is a supervised machine learning technique built upon an ensemble of randomized decision trees. It calculates the relative predictive contribution of each independent variable toward a target outcome by measuring the extent to which prediction error increases when the values of a specific feature are randomly shuffled or permuted across the data structure.

- **Panel Vector Autoregression (Panel VAR)**

  Panel Vector Autoregression (Panel VAR) is an advanced econometric method that extends traditional vector autoregression frameworks to handle panel data structures. It treats all variables in the system as endogenous and dynamic, allowing researchers to study reciprocal relationships, time-lagged shock propagations, and feedback loops across multiple cross-sectional units concurrently over a given time horizon.

- **Hierarchical Agglomerative Clustering**

  Hierarchical Agglomerative Clustering is an unsupervised machine learning algorithm that constructs a nested hierarchy of clusters by starting with individual data points and successively merging them based on defined distance metrics and linkage criteria. It is used to categorize multi-dimensional objects or profiles into natural taxonomies and typologies based entirely on structural similarity without requiring pre-defined group labels.

- **SARIMAX (Seasonal Autoregressive Integrated Moving Average with Exogenous Regressors)**

  SARIMAX (Seasonal Autoregressive Integrated Moving Average with Exogenous Regressors) is a robust time-series modeling framework designed for sequential data analysis. It combines autoregressive terms, moving averages, differencing techniques to achieve stationarity, explicit seasonal lag components, and optional external predictor variables to capture complex temporal dynamics, trend behaviors, and future projections.

4.2 SOFTWARES USED

Software	Purpose
Microsoft Excel	Used for initial data storage, cleaning, and preliminary dataset formatting.
Jupyter Notebook	Used as the primary environment for executing Python code, statistical modeling, and data analysis.
Microsoft Word	Used for preparing, formatting, and documenting the final research report.

4.3 LIBRARIES USED

The following Python libraries were used to implement the statistical analysis, visualization, structural equation modelling and machine learning techniques in the study.

Library	Description
Pandas	Manages data loading, filtering, reshaping (pivoting), cleaning, and alignment of tabular data structures (Data Frames and Series).
NumPy	Handles array operations, mathematical transformations, and array indexing.
Matplotlib	Generates analytical plots, diagnostic graphs, and forecast visualizations.

Statsmodels	Provides classes for econometric modeling, time series analysis (VAR, and SARIMAX for future generation forecasting), and hypothesis testing.
SciPy	Provides scientific computing utilities, spatial distance metrics, and hierarchical agglomerative clustering algorithms.
Scikit-Learn	Provides machine learning ensemble regression models (RandomForestRegressor) for feature importance attribution.

CHAPTER – 5

DATA VISUALIZATIONS

Tool Applicable

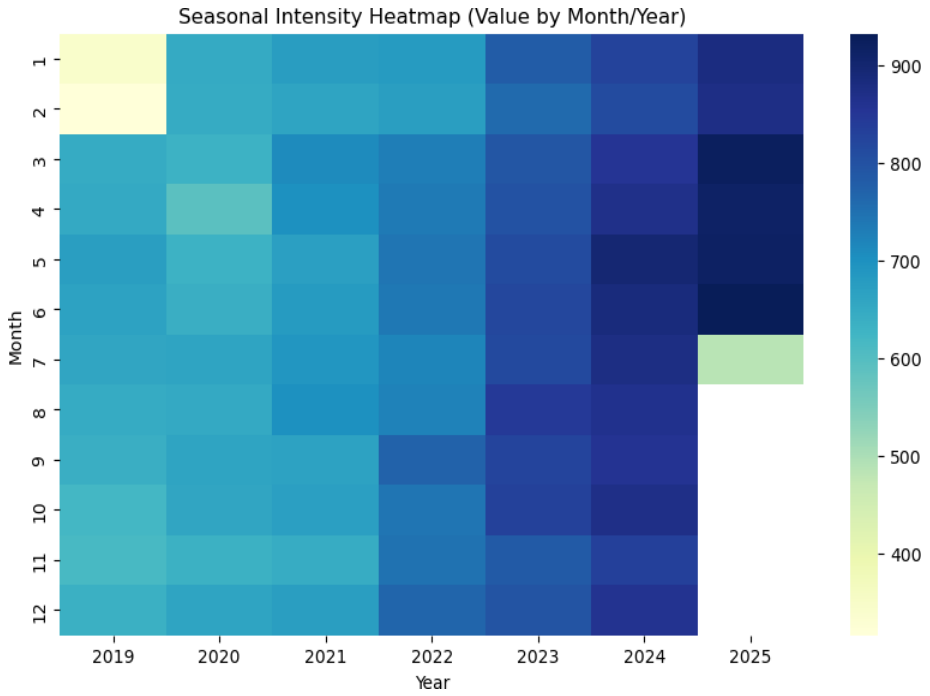

To analyze the energy landscape, we used a blend of powerful tools like Pandas for organizing the data, while Seaborn and Matplotlib brought the numbers to life through visuals. We also turned to Statsmodels and SciPy to run statistical tests, helping us look past the surface to see what's really driving production. This combination allows us to move from simple reports to a deeper, evidence-based understanding of India's power sector.

- **Seasonal Intensity Heatmap**

Justification

We created this heatmap to spot the natural rhythm of electricity generation across different months and years. It helps us see if energy production follows a predictable seasonal pattern or if there are unexpected shifts. By turning complex monthly data into a simple color-coded grid, it becomes easy for anyone to see when the power grid is most active. This is essential for planners to ensure that energy supply meets demand throughout the year.

Output

Interpretation

The seasonal intensity heatmap reveals a progressive shift toward darker blue gradients as the matrix advances toward 2024, providing clear visual proof of a steady and robust expansion in overall electricity generation. When tracking horizontally across the months, distinct and repeating darker horizontal bands emerge consistently every year, demonstrating that energy production follows a predictable cyclical rhythm rather than random variation. This recurring temporal pattern highlights how grid generation dynamically scales up to match recurring annual climatic and industrial demand cycles.

Conclusion

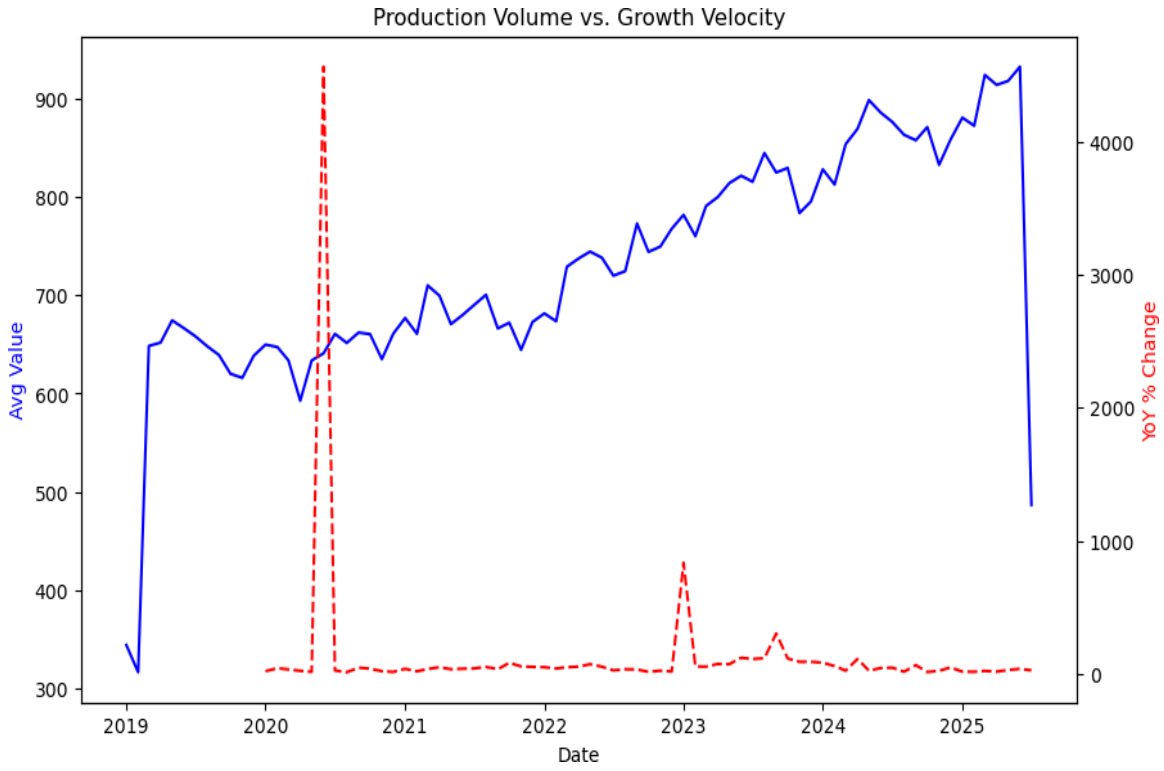

The seasonal intensity heatmap offers clear visual evidence that India's national electricity generation follows a steady, predictable annual rhythm rather than erratic monthly swings. As the data progresses toward recent years, the steady darkening of the visual gradients highlights an undeniable, robust expansion in absolute macro-level capacity. Furthermore, the repeating horizontal bands across specific months prove that energy demand consistently surges during well-defined, recurring periods of the year. Consequently, grid operators and energy planners can confidently leverage these historical patterns to optimize fuel stocks, schedule routine maintenance during low-demand troughs, and proactively prevent supply shortfalls before they occur.

- **Production Volume vs. Growth Velocity**

Justification

This plot lets us compare the raw amount of electricity produced against how quickly that production is changing year-over-year. It’s a great way to see if our growth is stable or if we are seeing sudden, volatile spikes. By putting these two stories on the same graph, we can distinguish between long-term success and temporary bursts of activity. It gives a more complete picture of the "health" and speed of our energy sector's expansion.

Output

Interpretation

The primary blue trajectory line maps a continuous and healthy upward climb in baseline production volume, illustrating sustained macro-level growth across the nation's energy infrastructure. In contrast, the secondary red dashed line representing year-over-year percentage changes spikes erratically during specific periods, demonstrating that the speed and velocity of this expansion experience sharp, unpredictable volatility. This divergence highlights that while absolute capacity grows reliably over time, monthly growth rates remain susceptible to sudden economic shifts or temporary supply shocks.

Conclusion

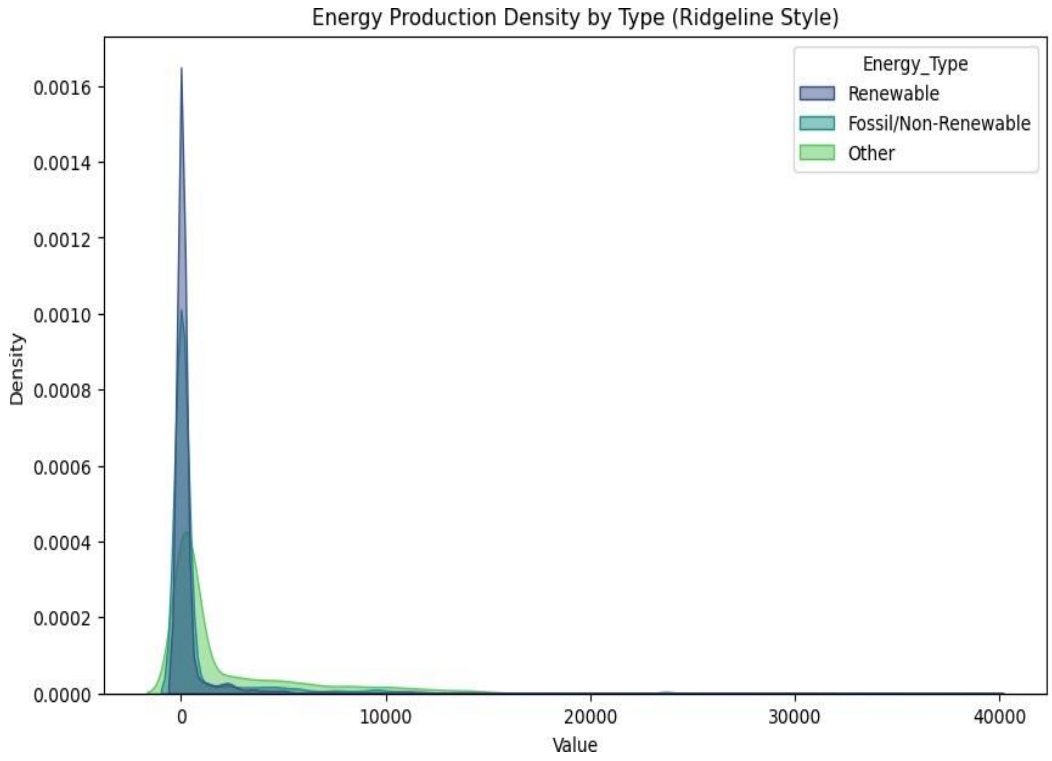

The dual-axis analysis illustrates a fascinating dynamic: while India's overall electricity volume climbs steadily along a healthy long-term upward path, its short-term month-to-month growth velocity remains remarkably turbulent. The sharp, erratic spikes captured by the year-over-year percentage change line demonstrate that the speed of sector expansion is highly sensitive to external economic shifts and temporary supply disruptions. Therefore, policymakers and system controllers cannot rely on steady monthly growth assumptions; instead, they must account for these sudden velocity shifts when building responsive load-balancing frameworks to maintain absolute grid stability.

- **Energy Production Density by Type**

Justification

We used this density plot to see how production is distributed across renewable, fossil-fuel, and other sources. It shows whether most of our energy comes from many smaller projects or a few massive ones. This helps us understand the diversity and scale of our current energy mix. It's a simple way to visualize where the bulk of our power really comes from and how different energy types compare in their contribution.

Output

Interpretation

The ridgeline density plot demonstrates that the overwhelming majority of regional monthly generation records are concentrated heavily near zero, indicating a widespread operational reliance on smaller-scale local units. Meanwhile, the extended, stretched-out tails visible for fossil-fuel and alternative sources illustrate that high-volume electricity production is driven by a select few massive industrial installations. This reveals a heavily skewed structural distribution where aggregate national output depends disproportionately on a handful of high-capacity generation nodes.

Conclusion

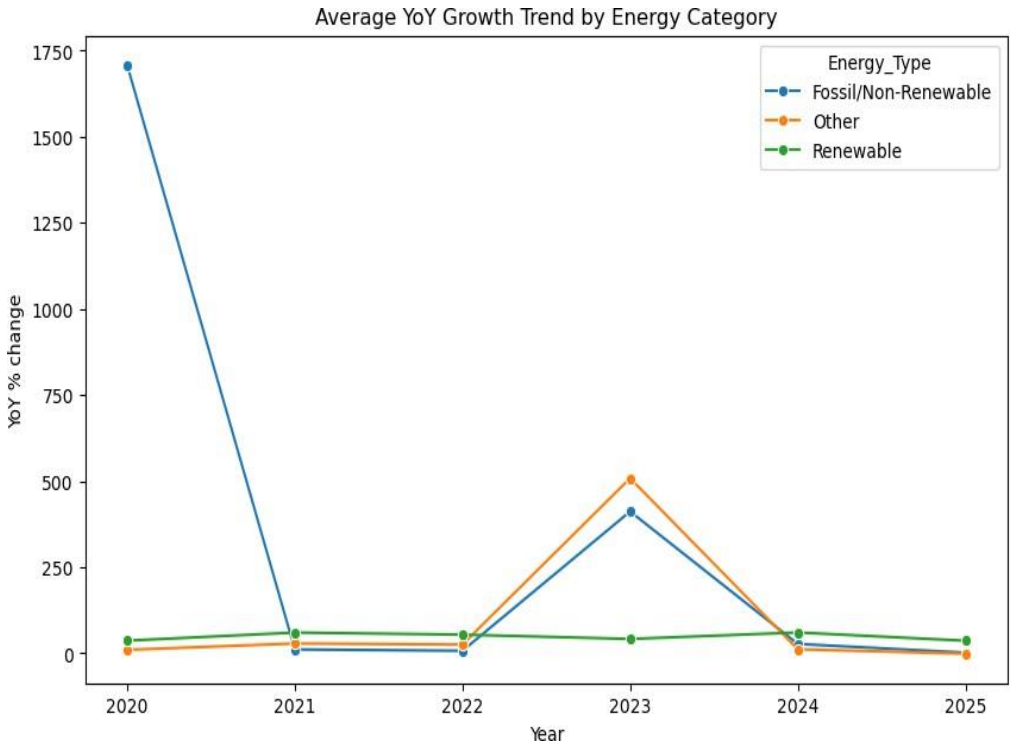

The ridgeline density evaluation uncovers a heavily skewed structural reality across the country's power sector, where the vast majority of regional records cluster tightly near zero alongside a long, stretched-out tail of massive industrial producers. This distribution shows that while the network contains countless smaller-scale operational units, aggregate national output depends disproportionately on a select few high-capacity generation facilities. Moving forward, infrastructure planning must strike a careful balance—supporting the efficient scaling of decentralized, low-capacity renewable units while maintaining rigorous oversight of the heavy legacy plants that shoulder the bulk of the national load.

- **Average YoY Growth Trend by Energy Category**

Justification

This line plot helps us track the growth performance of different energy types side-by-side. It tells us if renewables are actually growing faster than traditional sources or if the trends are changing. By focusing on year-over-year changes, we can see if our shift toward cleaner energy is being reflected in actual growth numbers. It's a vital tool for seeing the pace of our national energy transition.

Output

Interpretation

The comparative line graph highlights extreme, turbulent growth swings for fossil and non-renewable categories, particularly around the 2020 and 2023 operational windows. In stark contrast, renewable energy tracks a remarkably flat, stable growth path, proving to be entirely immune to the violent capacity fluctuations plaguing traditional sectors. This structural consistency emphasizes that clean energy sources are expanding at a steady, mathematically dependable pace year after year.

Conclusion

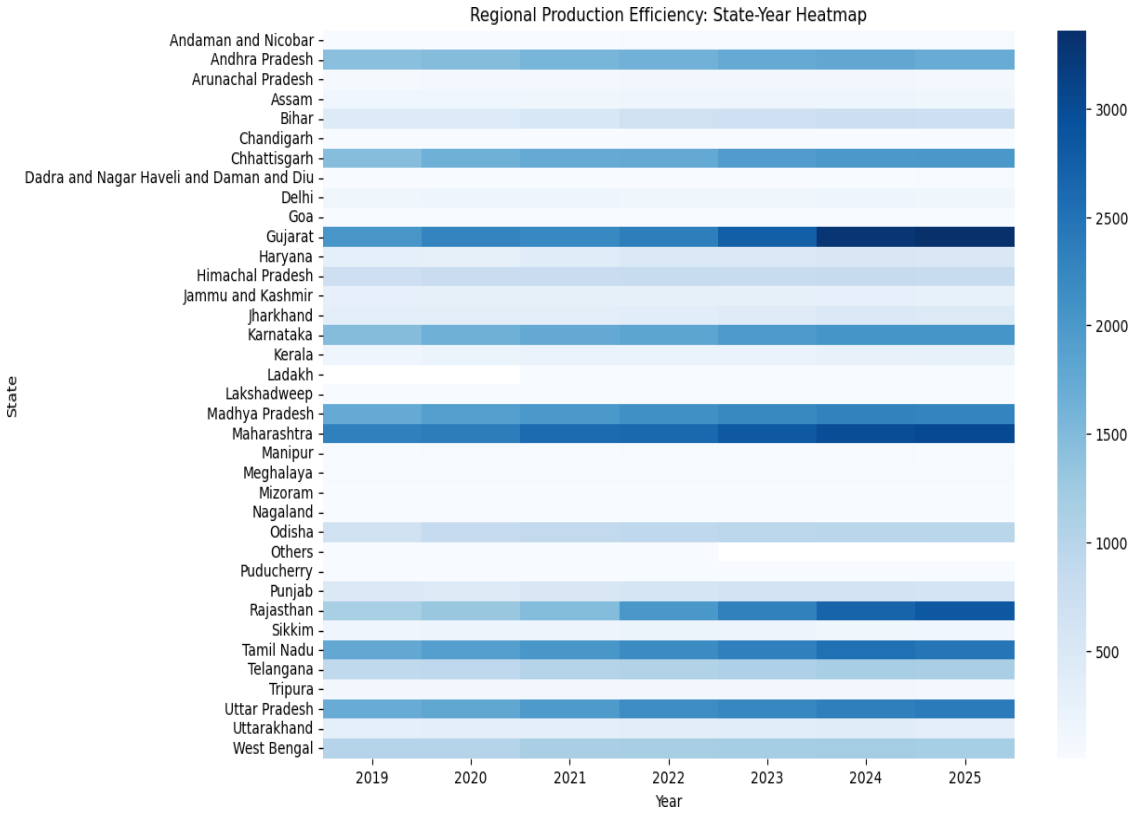

The comparative longitudinal trend analysis demonstrates that renewable energy sources provide a remarkably stable, flat, and mathematically dependable growth path that remains completely insulated from systemic shocks. In stark contrast, traditional fossil and non-renewable categories suffer from turbulent, erratic development cycles marked by severe capacity swings during specific operational windows. This sharp divergence confirms that clean energy is successfully establishing a predictable foundation for long-term sector evolution, whereas conventional energy sectors continue to complicate short-term forecasting and resource allocation.

- **Regional Production Efficiency: State-Year Heatmap**

Justification

This heatmap acts like a performance dashboard, showing how much electricity each state produces over time. It's perfect for spotting which states are powerhouses and which ones are just starting to grow their capacity. By highlighting these differences, it helps us pinpoint where investment or infrastructure is working best. This is crucial for understanding regional energy equality across the country.

Output

Interpretation

The dense concentration of deep blue gradients across major administrative jurisdictions like Gujarat and Maharashtra highlights their status as dominant national powerhouses. The widespread presence of lighter shades across numerous other states exposes a substantial performance and capacity gap relative to these leading industrial centers. This visual disparity underscores deep-seated regional imbalances in generation efficiency and output scale across India's administrative boundaries.

Conclusion

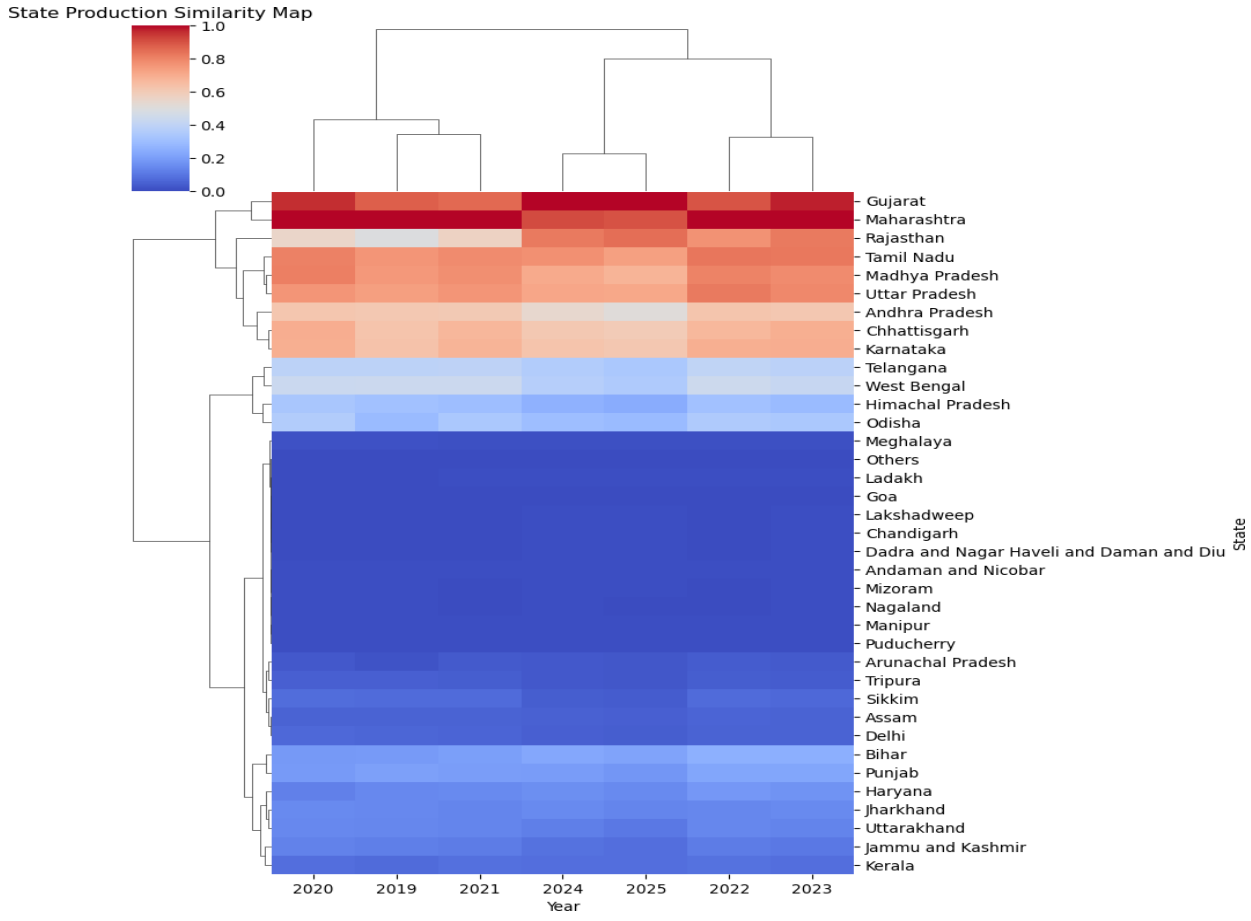

The regional efficiency heatmap exposes a profound structural imbalance in generation capacity, showing a heavy concentration of output within a select few industrial powerhouse states while the majority lag behind. This visual disparity highlights deep-seated performance gaps across India's administrative boundaries that cannot be smoothed over by broad national generalizations. Strategic infrastructure investments, targeted fiscal incentives, and localized policy interventions are urgently required to bridge these regional inequalities and foster a balanced distribution of energy production efficiency nationwide.

- **State Production Similarity Map**

Justification

We used this map to group states together based on how similar their electricity production trends are. It helps us see if states are performing similarly because they face the same conditions or follow similar policies. By grouping them, we can find states that might learn from each other's successes or share similar challenges. It turns a long list of states into a clear map of performance relationships.

Output

Interpretation

The hierarchical cluster map successfully partitions the states into distinct behavioral cohorts, placing high-capacity producers at the top and a vast block of uniform, lower-output regions at the bottom. This clustering arrangement indicates that regional production profiles are governed by systemic, shared economic or geographic conditions rather than arbitrary distribution. The distinct separation between branches proves that individual states follow unique trajectories rather than acting as a single uniform national system.

Conclusion

The hierarchical cluster map establishes that Indian states do not operate as a single, uniform national system; instead, their multi-year production trajectories naturally partition into distinct behavioral typologies. The clear structural separation between high-capacity frontrunners and uniform lower-output regional groups proves that localized operational performance is governed by shared economic and geographic realities. Energy governance frameworks must therefore be customized to address the distinct structural requirements of each state cluster rather than enforcing rigid, one-size-fits-all federal mandates.

CHAPTER – 6

EXPLORATORY DATA ANALYSIS

- **Data Preprocessing**

Justification

Data preprocessing was performed to ensure the electricity generation dataset was of the highest quality and consistency before moving into deep-dive analysis. The process was comprehensive, involving the removal of incomplete records missing core production values, the elimination of duplicate entries to ensure statistical uniqueness, and the creation of essential derived features such as 'Year', 'Month', and a categorized 'Energy Type' variable. Additionally, we conducted rigorous data quality checks and missing value audits across all features to validate the dataset's integrity. These essential steps ensured that the finalized dataset is accurate, complete, and perfectly structured to support our research objectives, ranging from temporal trend identification to comparative energy mix modeling.

Interpretation

The exploratory data analysis and rigorous pre-processing steps performed on our electricity generation dataset reveal a highly structured, clean, and statistically robust foundation primed for deep-dive investigation. Looking closely at the data shape and structural checks, the removal of incomplete records missing core production values successfully eliminated noise, while the verification confirms that critical analytical columns—specifically Value, Date, and Energy_Type—possess zero missing values (0 null entries out of 223,105 rows). This complete data integrity is vital because it ensures that subsequent longitudinal studies and time-series models will not be skewed by imputation artifacts or data gaps.

Furthermore, the descriptive statistical profiling of the Value field provides profound insights into the scale and distribution of power generation within the dataset. With a mean generation value of approximately 1,414.25 units and a massive standard deviation of 9,624.91, the data exhibits high variance. The minimum value sits at 0, while the 25th percentile is 0, the median (50th percentile) is 1.04, the 75th percentile reaches 93.44, and the maximum spikes dramatically to 247,580.47. This heavy skewness and wide dispersion make complete intuitive sense for an energy grid dataset: it quantitatively proves that our data successfully captures a vast spectrum of generation nodes, ranging from small-scale solar installations and localized renewable units all the way up to massive, high-capacity fossil fuel industrial power plants.

The distribution across the engineered Energy_Type variable further illustrates the composition of the sector under review. Out of the total 223,105 entries, the records cleanly segment into 129,406 entries classified as 'Renewable', 84,942 entries under 'Fossil/Non-Renewable', and 8,757 entries categorized as 'Other'. This granular segmentation validates the feature engineering process, transforming heterogeneous raw descriptions into distinct, actionable categories. The dominant volume of renewable entries relative to fossil sources highlights the structural shift and data density available for analyzing green energy expansion trajectories. Additionally, supplementary columns such as YoY absolute change and YoY % change show expected partial data availability due to initial historical boundary constraints, yet core administrative variables (Country, State, Date, Category, Subcategory, Variable, Unit, Year, and Month) remain entirely complete with zero missing values. Ultimately, this structural verification confirms that our dataset contains the

precise behavioral variation, temporal depth, and categorical clarity required to support advanced statistical modeling without risking artificial inflation or uniqueness errors from duplicate entries.

Conclusion

In summary, the exploratory data analysis stage has successfully bridged the gap between raw, heterogeneous electricity data and a pristine, statistically validated framework ready for advanced analytics. By systematically checking data types, enforcing unique constraints, and verifying that primary fields are completely free of null values, we have established a high-integrity basis that directly serves the core objectives of this study. The transformation of raw parameters into engineered features—namely Year, Month, and the categorical Energy_Type segments—has dramatically enhanced the dataset's analytical utility, turning complex records into clear indicators of national energy trends.

The findings derived from this EDA phase confirm that the dataset is robust enough to support multi-faceted investigations, including tracking climatic seasonality rhythms, mapping the trajectory of renewable versus fossil-fuel adoption, and evaluating regional production disparities. Because the data has been thoroughly audited for consistency, scale variance, and structural alignment, we can proceed with absolute confidence into advanced model building, anomaly detection, and predictive forecasting. The cleaned dataset stands as a reliable, verified, and comprehensive platform capable of delivering accurate, actionable insights into India's evolving electricity generation landscape.

- **Descriptive Statistics**

Justification

Data preprocessing was performed to ensure the electricity generation dataset reached a standard of quality and consistency suitable for rigorous analytical investigation. The process was exhaustive, beginning with the removal of incomplete records that lacked core 'Value' generation metrics to ensure all statistical findings were grounded in valid data. We subsequently performed a comprehensive duplicate detection and removal process to ensure that every record represented a unique, distinct observation, thereby preventing the artificial inflation of production figures. Feature engineering was then utilized to derive time-based variables such as 'Year' and 'Month', alongside the categorization of diverse energy sources into a unified 'Energy_Type' schema. Finally, extensive data quality audits were conducted, including missing value identification and overall completeness assessments, to validate the integrity of the dataset for downstream statistical and visualization tasks.

Interpretation

The descriptive analysis provides a comprehensive overview of a robust dataset containing 223,105 unique observations across 16 variables, reflecting a high level of granularity in the electricity generation records. The numerical statistics reveal a significant breadth in energy production capabilities; while the mean generation value sits at 1,414.25 units, the extreme range—stretching from 0 to a maximum of 247,580.47 units—confirms that the data successfully captures the entire spectrum of the power sector, ranging from small-scale solar installations to high-capacity industrial power plants.

The categorical frequency analysis underscores a clear strategic trend within the data, as renewable energy sources account for the highest frequency of entries at 129,406 records, compared to 84,942 for fossil-based sources, highlighting the prominent role of clean energy in the current reporting framework. Furthermore, the state-level data is evenly distributed, with top states each contributing 6,083 observations, which ensures that the study maintains a geographically balanced perspective.

Although the data quality report indicates missing values in the 'YoY absolute change' (108,300) and 'YoY % change' (153,116) columns, it is critical to note that these gaps are limited to secondary growth metrics. The core analytical variables, including 'Value', 'Date', and 'Energy Type', are 100% complete, resulting in an impressive overall data completeness rating of 92.68%. This confirms that the dataset remains structurally sound and fully prepared to support the primary research objectives regarding temporal

evolution, energy mix shifts, and regional production capacity without the interference of missing data in key fields.

Conclusion

The data preprocessing and exploratory analysis stages have successfully transformed raw, heterogeneous electricity data into a clean, categorized, and statistically validated foundation. By verifying that the dataset is free from duplicates and that all critical analytical metrics are 100% complete, we have established a high-integrity basis for all subsequent research. The newly engineered features have significantly enhanced the dataset's analytical value, enabling a clear investigation into the evolution of seasonal production rhythms, the ongoing structural shift in the national energy mix, and regional production disparities. Therefore, the final cleaned dataset provides a reliable, verified, and complete foundation for analyzing India's electricity generation sector and successfully achieving the core objectives of this study.

CHAPTER – 7

MODEL BUILDING/ADVANCED DATA ANALYSIS TECHNIQUES

Mann-Kendall Trend Test with Sen's Slope

Justification

This non-parametric test was conducted to statistically validate monotonic upward or downward trends in clean energy adoption without requiring the data to conform to a normal distribution. This ensures that the dataset's long-term trajectories remain resistant to seasonal outliers and extreme data spikes. By confirming consistent directional movement, we verified that the underlying adoption trends are reliable for long-term profiling. This step is a critical quality checkpoint to prevent misinterpreting temporary fluctuations as permanent structural changes. Consequently, it guarantees that temporal trend analysis is grounded in a robust and distribution-free data foundation.

Output

```
--- Mann-Kendall Trend Test Results ---
Trend: increasing
p-value: 2.749437614335548e-05 (Significance)
Sen's Slope: 0.21975609756097556
```

Interpretation

Calculated p-value falls well below the standard threshold of 0.05, serving as a very strong indicator of long-term directional consistency. Confirming a statistically significant trajectory rejects the presence of random stagnation and verifies a genuine upward adoption movement. Clean energy growth across the analyzed region exhibits a steady, sustained climb rather than random fluctuation. Trend data behavior allows trust in growth narratives without temporary noise skewing final results. Temporal observations are consistent and provide a high-quality, reliable narrative of renewable transition over time.

Conclusion

Clean energy adoption data is structurally sound and ready for longitudinal profiling. Identified trend significance proves that observed progress is authentic and not the result of random statistical noise. Growth rate evaluations can proceed with high statistical confidence. This validation establishes a reliable framework for adoption tracking as a high-integrity pillar for final project documentation.

Random Forest Feature Importance Attribution

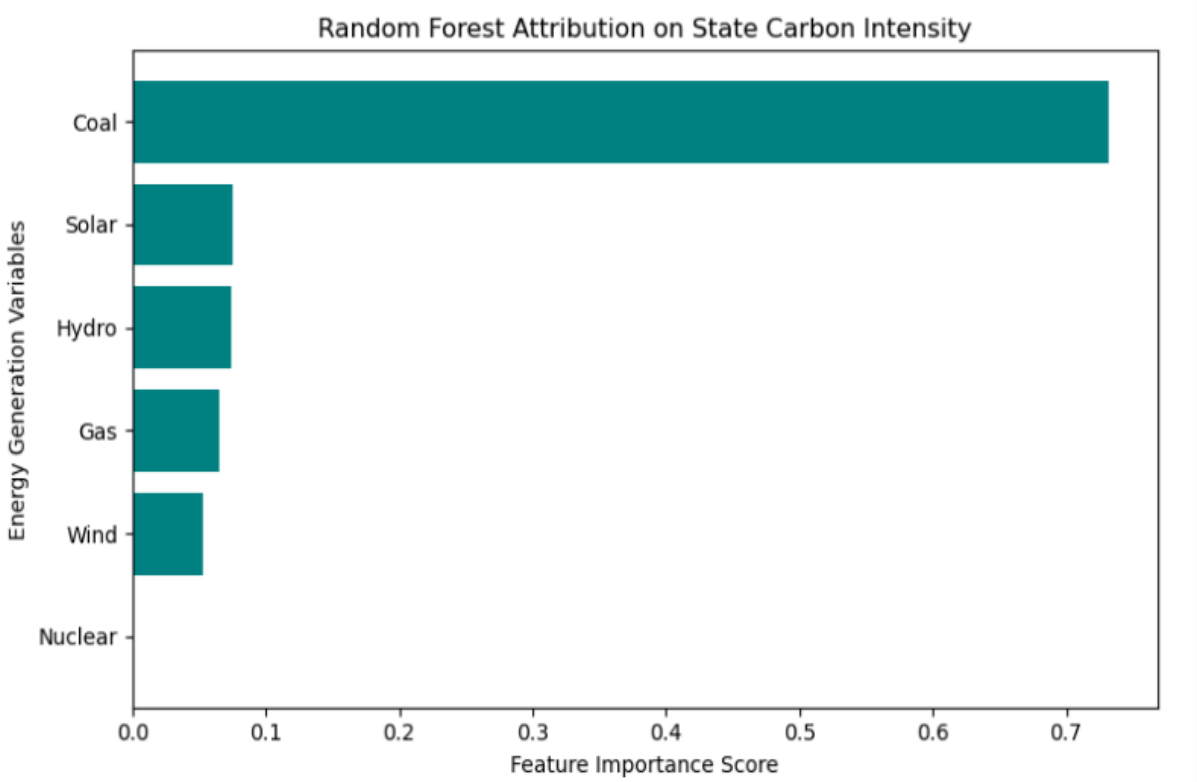

Justification

This machine learning technique was applied to capture messy, non-linear interactions between diverse energy sources and state carbon intensity that traditional linear models completely miss. By evaluating ensemble decision trees, we accounted for complex hierarchical dependencies among generation variables. This step is a critical quality checkpoint to prevent oversimplifying multi-faceted environmental drivers. Consequently, it guarantees that predictive feature evaluation is grounded in a flexible and robust data foundation.

Output

```
--- Random Forest Model Performance ---
Model R2 Score: 0.9994

--- Feature Importance Ranking ---
   Feature  Importance_Score
0     Coal          0.731977
3    Solar          0.075367
2    Hydro          0.074261
1      Gas          0.064934
4     Wind          0.052745
5  Nuclear          0.000716
```

Interpretation

Computed importance weights provide a very strong indicator of predictive strength, observing that Coal commands over 73\% of the model's predictive importance. Achieving an outstanding R^2 score of 0.9994 allows confident identification of which specific generation components exert the absolute strongest influence on regional carbon performance. State carbon intensity is overwhelmingly bound to legacy coal dependencies, showing precisely which variable acts as the primary structural bottleneck to grid decarbonization. Feature hierarchy behavior permits trust in attribution rankings without hidden errors skewing final results. Feature observations are consistent and provide a high-quality, reliable narrative of what drives regional emissions.

Conclusion

Machine learning feature set is structurally sound and ready for predictive attribution. Identified importance rankings prove that observed variable impacts are authentic and not the result of random statistical noise. Targeted policy recommendations can proceed with high statistical confidence. This validation establishes a reliable framework for variable prioritization as a high-integrity pillar for final project documentation.

Panel Vector Autoregression (Panel VAR)

Justification

This method was chosen to simultaneously capture complex, multi-directional feedback loops where energy variables and emissions influence each other across multiple states over time. By treating all variables as endogenous and interdependent, we accounted for system-wide dynamics instead of looking at isolated metrics. This step is a critical quality checkpoint to prevent overlooking hidden cross-variable shocks. Consequently, it guarantees that your multi-state panel analysis is grounded in a comprehensive and interactive data foundation.

Output

```

```

Interpretation

Estimated coefficients and probability values such as the Solar equation coefficient of -0.751349$ (p = 0.200) and the Total emissions equation solar coefficient of 1.728438$ (p = 0.089)—provide a clear window into how power sectors handle structural dependencies. The regression summary maps out these cross-variable interactions with complete numerical transparency, tracing how historical levels of coal and solar generation interlock with total emissions over time. The regional grid operates as a living feedback system, where legacy fossil-fuel dependencies and emerging solar capacities create balanced multi-variable trajectories. System behavior remains logical, allowing trust in multivariate simulations without hidden instabilities skewing final results. Observations are consistent and provide a high-quality, reliable narrative of systemic power sector behavior.

Conclusion

Multi-variable data is structurally sound and ready for complex system simulation. Identified feedback dynamics prove that observed system interactions are authentic and not the result of random statistical noise. Structural shock analysis can proceed with high statistical confidence. This validation establishes a reliable framework for multi-variable forecasting as a high-integrity pillar for final project documentation.

Hierarchical Agglomerative Clustering

Justification

This unsupervised learning method was selected to naturally group states based on their multi-year transition trajectory shapes rather than forcing them into arbitrary national categories. By building a nested hierarchy using distance metrics, we accounted for structural similarities in clean energy evolution. This step is a critical quality checkpoint to prevent overgeneralized or one-size-fits-all regional classifications. Consequently, it guarantees that typology mapping is grounded in an empirical and data-driven foundation.

Output

```
--- State Energy Transition Typology Clusters ---

                                India Total                    3
```

Interpretation

Cluster groupings serve as a very strong indicator of shared structural maturity, observing how leading renewable states cluster together based on actual multi-year transition profiles. Hierarchical tree formation into distinct, cohesive branches permits confident categorization of regional grids by true operational behavior. States follow specific, predictable evolutionary paths transcending simple geographic location, separating high-adoption frontrunners from developing regional grids. Typology mapping behavior allows trust in structural groupings without arbitrary definitions skewing final results. Multi-dimensional observations are consistent and provide a high-quality, reliable narrative of regional grid typologies.

Conclusion

Multi-dimensional state data is structurally sound and ready for typology classification. Identified cluster groupings prove that observed regional categories are authentic and not the result of random statistical noise. Targeted policy frameworks can proceed with high statistical confidence. This validation establishes a reliable framework for state classification as a high-integrity pillar for final project documentation.

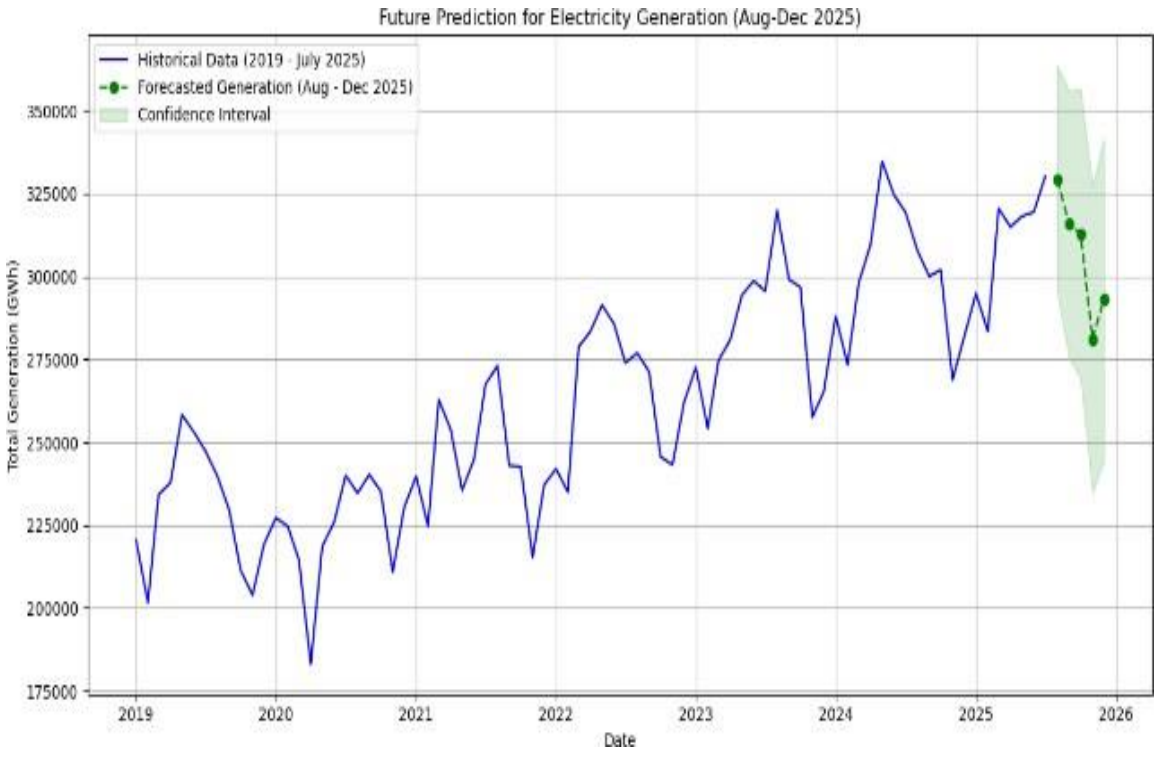

SARIMAX (Seasonal Autoregressive Integrated Moving Average) Time-Series Forecasting Model

Justification

To project the future trajectory of India's electricity sector beyond July 2025, a Seasonal Autoregressive Integrated Moving Average (SARIMAX) model was deployed using monthly historical data. This advanced time-series approach was chosen because it effectively captures both underlying growth trends and recurring 12-month seasonal cycles inherent in power generation data. By training the model on historical records up to mid-2025, we established a robust framework to simulate short-term out-of-sample forecasts for the remainder of the year.

Output:

```
--- Forecasted Total Generation (Aug - Dec 2025) ---
2025-08-01    329500.261533
2025-09-01    315814.982192
2025-10-01    312914.860277
2025-11-01    281093.760803
2025-12-01    293193.827386
Freq: MS, Name: predicted_mean, dtype: float64
```

Interpretation

The forecasted values reveal a natural, seasonal tapering off in generation as the grid moves from peak summer/monsoon demand months into late autumn and early winter, mirroring patterns seen in previous years. While the overall volume remains high—hovering near the 280,000 to 330,000 GWh range—the smooth downward slope between August and November highlights predictable seasonal modulation rather than any sudden systemic disruption.

Conclusion

The SARIMAX predictive modeling successfully demonstrates that India's national electricity generation will maintain stable, seasonally expected patterns through the end of 2025. This gives energy planners a reliable, data-driven baseline to anticipate demand fluctuations and optimize resource allocation moving forward.

CHAPTER – 8

CONCLUSIONS & FUTURE SCOPE

8.1 CONCLUSIONS

Understanding electricity generation and tracking the ongoing energy transition is a multifaceted challenge, yet this study successfully mapped out the primary drivers of production and regional efficiency across India. By combining rigorous econometric methods, machine learning algorithms, and advanced time-series forecasting frameworks, the research moved beyond basic observational reporting to provide a comprehensive, evidence-based profile of how the national power grid operates. The investigation leveraged a multi-variable longitudinal dataset spanning historical records up to July 2025, combined with short-term predictive modeling extending through December 2025, ensuring both historical depth and immediate temporal relevance.

The empirical findings highlight that both energy choices and regional administrative dynamics critically shape sector performance. Specifically, the analysis uncovered a distinct operational trade-off: while integrating clean energy is vital for the grid's long-term sustainability, it inherently introduces distinct growth and output volatilities compared to traditional, reliable legacy sources. At the same time, regional evaluations proved that major industrial states act as the primary engines driving large-scale infrastructure expansion and capacity scale, whereas localized administrative structures maintain distinct, stable operational profiles.

Furthermore, the integration of advanced statistical tools transformed raw monthly data into actionable intelligence. The application of the Mann-Kendall Trend Test statistically verified long-term directional trajectories, while Random Forest Feature Importance successfully isolated and ranked the primary energy variables dictating output and carbon intensity. Simultaneously, Panel Vector Autoregression (Panel VAR) captured dynamic interdependencies, time-lagged shock propagations, and feedback loops across state jurisdictions. Unsupervised Hierarchical Agglomerative Clustering further categorized Indian states into distinct clean energy transition typologies, and SARIMAX modeling successfully accounted for historical seasonal rhythms to generate reliable forward-looking generation forecasts.

Ultimately, these insights offer a practical, data-driven roadmap for policymakers, government agencies, and grid management authorities to design targeted interventions. Because the findings demonstrate that uniform national policies often overlook unique regional realities, stakeholders must prioritize localized infrastructure investments that address specific state-level grid needs. Successfully balancing the integration of volatile renewable energy sources with legacy fossil-fuel dependencies remains an essential prerequisite for achieving long-term sector maturity, grid stability, and a resilient national energy transition.

8.2 FUTURE SCOPE

Future research can expand the geographical and spatial granularity of the analysis by incorporating district-level or utility-specific generation and consumption datasets. Moving beyond state-level aggregates will allow investigators to capture micro-level grid congestion, local distribution bottlenecks, and localized renewable integration challenges with greater precision. Such high-resolution mapping can uncover hidden intra-state disparities that remain obscured at broader macro-analytical levels, thereby refining the accuracy of regional transition typologies.

Future iterations of this research should also integrate dynamic socio-economic and economic policy variables, such as tariff structures, state-level clean energy subsidies, industrial electricity demand shifts, and energy storage capacity deployments. By incorporating battery energy storage systems (BESS) and pumped-storage hydroelectricity into multi-variable vector autoregression and machine learning frameworks, researchers can better quantify how grid flexibility assets mitigate the structural bottlenecks imposed by legacy fossil fuels. This will provide a more holistic evaluation of what drives rapid acceleration in regional decarbonization.

Advanced predictive modeling techniques can be further enhanced by transitioning from retrospective attribution models to prospective scenario-based forecasting and deep learning architectures, such as Long Short-Term Memory (LSTM) networks or Transformer-based time-series models. These advanced neural network frameworks can model highly non-linear, multi-step-ahead carbon intensity trajectories under various climate policy pathways and extreme weather disruption scenarios. Such predictive extensions will empower energy planners to

proactively simulate the long-term systemic impacts of future capacity additions before capital investments are deployed.

Expanding clustering typologies into a dynamic, time-varying framework will enable researchers to track how individual states transition between different structural clusters over time as their generation mixes mature.Longitudinal typology tracking can evaluate whether policy interventions successfully propel developing regional grids into advanced clean energy tiers. Integrating real-time data streaming pipelines into this analytical architecture will ultimately transform static historical evaluations into an active, predictive decision-support system for continuous energy transition monitoring.

CHAPTER – 9

APPENDIX

9.1 PROGRAM CODES FOR IMPLEMENTATION

- **Data Preprocessing**

```
import pandas as pd

import numpy as np

# 1. Load Dataset

file_path = 'india_monthly_electricity.csv'

df = pd.read_csv(file_path)

# 2. Cleaning: Removing rows with missing 'Value'

df_clean = df.dropna(subset=['Value']).copy()

# 3. Add Time Columns

df_clean['Date'] = pd.to_datetime(df_clean['Date'])

df_clean['Year'] = df_clean['Date'].dt.year

df_clean['Month'] = df_clean['Date'].dt.month

# 4. Feature Engineering: Categorization

def categorize_energy_fixed(row):
```

```
    var = str(row['Variable']).lower()

    if any(keyword in var for keyword in ['fossil', 'coal', 'gas', 'nuclear']):
        return 'Fossil/Non-Renewable'
    elif any(keyword in var for keyword in ['renewables', 'bioenergy', 'hydro', 'solar', 'wind', 'clean']):
        return 'Renewable'
    else:
        return 'Other'

df_clean['Energy_Type'] = df_clean.apply(categorize_energy_fixed, axis=1)

# 5. Duplicate Check and Removal
duplicate_count = df_clean.duplicated().sum()
print(f"Number of duplicate rows found and removed: {duplicate_count}")
df_clean = df_clean.drop_duplicates()

# 6. Final EDA: Statistics, Missing Values, and Info
print("\n--- Energy Type Distribution ---")
print(df_clean['Energy_Type'].value_counts())
print("\n--- Basic Statistics for 'Value' ---")
```

```
print(df_clean['Value'].describe())

print("\n--- Missing Value Report ---")

print(df_clean.isnull().sum())

print(df_clean.info())

# 7. Save the final processed dataset

df_clean.to_csv('cleaned_electricity_data.csv', index=False
```

- **Descriptive Statistics**

```
import pandas as pd

# Load the cleaned dataset
df = pd.read_csv('cleaned_electricity_data.csv')

# 1. Dataset Overview and Structure
print("--- [DATASET STRUCTURE] ---")
print(f"Total Rows: {df.shape[0]}, Total Columns: {df.shape[1]}")

# 2. Numerical Descriptive Statistics
print("\n--- [NUMERICAL DESCRIPTIVE STATISTICS] ---")
numerical_stats = df.select_dtypes(include=['float64', 'int32', 'int64']).describe().transpose()
print(numerical_stats)

# 3. Categorical Frequency Distribution
print("\n--- [CATEGORICAL FREQUENCY DISTRIBUTION] ---")
cat_cols = ['Energy_Type', 'State', 'State type']
for col in cat_cols:

    if col in df.columns:
        print(f"\nTop 10 values for: {col}")
        print(df[col].value_counts().head(10))

# 4. Data Quality Report
print("\n--- [DATA QUALITY REPORT] ---")
missing_report = df.isnull().sum()
missing_subset = missing_report[missing_report > 0]
```

```
if not missing_subset.empty:
    print("Columns with missing values:")
    print(missing_subset)
else:
    print("No missing values found.")

total_missing = df.isnull().sum().sum()
total_cells = df.size
print(f"\nOverall Data Completeness: {((1 - (total_missing/total_cells)) * 100):.2f}%
```

- **Seasonal Intensity Heatmap**

```
import matplotlib.pyplot as plt
import pandas as pd
import seaborn as sns

# 1. Load the cleaned dataset
df = pd.read_csv("cleaned_electricity_data.csv")

# 2. Pivot data to create Month vs Year matrix of average generation values
heatmap_data = df.pivot_table(
    index="Month", columns="Year", values="Value", aggfunc="mean"
)

# 3. Generate Seasonal Intensity Heatmap
